Chapter 1

Introduction

1.1 Combinatorial Generation: Looking at All the Possibilities

Combinatorial generation is defined as the exhaustive listing of combinatorial objects of various types. Frank Ruskey duly notes in his book *Combinatorial Generation* that the phrase “Let’s look at all the possibilities” sums up the outlook of his book and the field as a whole [?]. Examining all possibilities fitting certain criteria is frequently necessary in fields ranging from mathematics to chemistry to operations research. Combinatorial generation as an area of study seeks to find an underlying combinatorial structure to these possibilities and utilize it to obtain an algorithm to efficiently enumerate an appropriate representation of them [?].

A quintessential result of the combinatorial generation in practice is Frank Gray’s reflected binary code, or Gray code. Gray codes give a “reflected” ordering of binary strings such that each successive string in the ordering differs from the previous string by exactly one bit. This contrasts from a lexicographic ordering of binary strings, in which a n -digit binary string can differ by up to n digits from its predecessor and will differ by approximately two (more precisely $\sum_{i=0}^n 2^i$, which is 1.9375 for 4 bit values and 1.996 for 8 bit values) bits on average¹. The binary reflected Gray code, therefore, provides an ordering that requires as many bit switches as the more intuitive lexicographic order. Binary reflected Gray codes are widely used in electromechanical switches to reduce error and prevent spurious output associated with asynchronous bit switches. Crucially, Frank Gray’s reflected binary code achieved a tangible benefit in error reduction through the use of an alternative method of enumerating binary strings. The technique of reflecting all or certain parts of a string to generate new strings has become one of the most widely used techniques in combinatorial generation.

¹Consecutive pairs of binary digits in lexicographic order will differ in the bit at position i with probability $\frac{1}{2^i}$. Therefore, the average number of differing bits between two binary strings of length n is $\sum_{i=0}^n 2^i$, which converges to 2 as n grows large.

Figure 1.1: Lexicographic (top), binary reflected Gray code (middle), and cool-lex (bottom) enumerations of 6-bit binary strings.

Individual strings are read vertically with the most significant bit at the top; white is 1.

1.2 Gray Codes for Strings, Lattice Paths and Trees

In this thesis, we are not concerned with counting combinatorial objects, but rather with efficiently ordering them. We aim to create a *Gray code* or *minimal change ordering* for these objects. Frank Gray’s reflected binary code used complementing a single bit as the minimal change between successive binary strings in its ordering. Other notions of minimal changes in strings are *adjacent-transpositions*, or *swaps*, which interchange two adjacent symbols in a string, and *shifts*, in which a single symbol in a string moved to another position. Our Gray codes for strings will use a slightly more restrictive type of shift: a *left-shift*, which moves a single symbol somewhere to the left within a string. More specifically, if $\alpha = a_1 a_2 \dots a_n$ is a string and $i < j$, then we let

$$\text{left}_\alpha(j, i) = a_1 a_2 \dots a_{i-1} a_j a_i a_{i+1} \dots a_{j-1} a_{j+1} a_{j+2} \dots a_n.$$

Our gray code for ordered trees will use *firstborn-shifts*, which shift the first child of one node to be the first child of another node.

1.3 Cool-Lex Order

Cool-lex order has introduced the idea of rotating sublists to enumerate languages. Different versions of cool-lex order have been shown to enumerate several sets of combinatorial objects, including binary strings, fixed weight binary strings, Dyck words, and multiset permutations. Cool-lex orders often lead to algorithms that are faster and simpler than standard lexicographic order. For example, the “multicool” package in R uses a loopless cool-lex algorithm to efficiently enumerate multiset permutations. The package started using cool-lex order for multiset permutations in version 1.1 and as of version 1.12 has been downloaded nearly a million times [?].

1.4 Goals of this Thesis

Cool-lex has been shown to provide a minimal-change cyclic ordering for the sets of fixed-weight binary strings, multiset permutations, binary and k-ary Dyck words, and other languages [?]. A common thread in the cool-lex algorithms for combinatorial generation is their focus on the *first increase* of string, or the longest prefix of a string such that each successive symbol in the prefix is less than or equal to the previous symbol in the string.

This thesis will examine the use of cool-lex orders to enumerate other languages. Among these are ordered trees, Lukasiewicz words, and Motzkin words.

Dyck, Motzkin, and Lukasiewicz paths all share bijections with various combinatorial objects. For example, Dyck paths of length $2n$ share a bijection with binary trees with n nodes. Ruskey and Williams found that the cool-lex successor rule for enumerating Dyck words corresponded directly to a loopless successor rule for enumerating binary trees with a constant number of pointer changes [?].

Chapter 2

Catalan Objects

Introduce all these things plus concepts/features that will be useful later. The Catalan numbers are one of the most ubiquitous sequences of numbers in mathematics. Named for mathematician Eugene Charles Catalan, the n^{th} Catalan number can be succinctly defined as the number of ways of triangulating a convex polygon with $n + 2$ sides. Figure 2.1 demonstrates this for the case of $n = 3$. The sequence of Catalan numbers for $n \geq 0$ can be defined mathematically as follows:

$$C_n = \frac{(2n)!}{n!(n+1)!} = 1, 1, 2, 5, 14, 42, 132, \dots \quad \text{OEIS A000108} \quad (2.1)$$

The Catalan numbers can also be expressed through a summation that hints at the recursive structure of many of the Catalan objects.

$$C_{n+1} = \sum_{k=0}^n C_k C_{n-k}, \quad C_0 = 1 \quad (2.2)$$

In the case of triangulated polygons, this summation can be derived as follows:

C_{n+1} is the way of triangulating a convex polygon with $n+3$ sides. Let \mathcal{P}_{n+3} be a convex $(n+3)$ -gon and let \mathcal{T} be a triangulation of \mathcal{P}_{n+3} . Fix an edge e in \mathcal{P}_{n+3} . Note that e lies between two vertices of \mathcal{P}_{n+3} . e must be in exactly one triangle in \mathcal{T} . Let T_i be the triangle in \mathcal{T} that contains e . T_i must have two of its vertices on the two vertices of e and one vertex that is another vertex in \mathcal{P}_{n+3} . There are $n+1$ other vertices of \mathcal{P}_{n+3} . Suppose the third vertex of T_i is $k+1$ vertices clockwise of e , where $0 \leq k \leq n$. Drawing T_i divides \mathcal{P}_{n+3} into 3 polygons: T_i , a $(k+2)$ -gon clockwise of T_i , and a $(n-k+2)$ -gon counterclockwise of T_i . This means that for each possible value of k , there is one way of triangulating T_i , C_k ways of triangulating the polygon clockwise of T_i , and C_{n-k} ways of triangulating the polygon counterclockwise of T_i . Therefore, there are $C_k * C_{n-k}$ ways of triangulating \mathcal{P}_{n+3} for each value of k . Therefore, there are $C_{n+1} = \sum_{k=0}^n C_k C_{n-k}$ total ways of triangulating \mathcal{P}_{n+3} . Figure 2.2 illustrates this process for the case of $n+1=6$.

The Catalan numbers count a remarkable number of interesting and useful combinatorial objects in bijective correspondence with triangulations of n -gons. Combinatorial objects counted by the Catalan numbers are referred to as *Catalan objects*. Richard Stanley's book *Catalan Numbers* gives hundreds of examples of Catalan objects as well as including a thorough history on the numbers and their study [?]. This thesis will focus primarily on three Catalan objects: Dyck words, binary trees, and ordered trees.

Figure 2.1: The $C_3 = 5$ triangulations of a polygon with $3 + 2 = 5$ sides.

Figure 2.2: Constructing C_6 , the number of ways to triangulate an octagon, from triangulations of smaller sub-polygons.

$$C_6 = \sum_{k=0}^5 C_k C_{6-k} = 42 + 14 + 10 + 10 + 14 + 42 = 132$$

2.1 Dyck Words and Paths

The language of binary Dyck words is the set of binary strings that satisfy the following conditions: The string has an equal number of ones and zeroes and each prefix of the string has at least as many ones as zeroes. The number of distinct Dyck words with n ones and n zeroes is equal to C_n . Dyck words with n ones and n zeroes are frequently referred to as Dyck words of *order* n . For example, the $C_2 = 2$ Dyck words of order 2 are 1100 and 1010.

Two common interpretations of Dyck words are balanced parentheses and paths in the Cartesian plane. If each one in a Dyck word is taken to represent an open parenthesis and each zero a closing parenthesis, the Dyck language becomes the language of balanced parentheses. Alternatively, the Dyck language can be interpreted as the set of paths in the Cartesian plane using $(1, 1)$ (northeast) and $(1, -1)$ (southeast) steps that start at $(0, 0)$ and never go below the x axis. In this case, each one in a Dyck word represents a $(1, 1)$ step and each zero represents a $(1, -1)$ step.

Figure ?? gives an illustration of each of these interpretations of Dyck words for $n = 4$.

2.2 Binary Trees

Binary trees are fundamental objects in computer science, and are commonly used for searching, sorting, and storing data hierarchically. A binary tree can be defined recursively as follows: The empty set ϕ is a binary tree. Otherwise a binary tree has a root vertex, a left subtree, and a right subtree, where each subtree is also a binary tree. A closely related object is an *extended binary tree*, which is a binary tree for which every non-leaf node has exactly two children.

Binary trees and extended binary trees are both counted by the Catalan numbers: C_n is the number of binary trees with n nodes and the number of extended binary trees with n internal nodes. A binary tree b with n nodes can be constructed from an extended binary tree e with n internal nodes by removing all leaves from the extended binary tree, leaving the n internal nodes as the only remaining nodes.

This process can be reversed to construct an extended binary tree with n internal nodes from a binary tree with n nodes. Given a binary tree b with n nodes, add two leaf children to every leaf in b and add one leaf child to every node in b with one child. Following these steps, every node originally in b is now an internal node, and therefore the constructed tree is an extended binary tree with n internal nodes.

2.3 Ordered Trees

An ordered tree is a tree for which each node can have an unrestricted number of children and the order of a node's children is significant. An ordered tree can be defined recursively as follows:

An ordered tree is a tuple (r, C) where r is a root node and C is either the empty set ϕ or an ordered sequence of children $(P_1 \dots P_m)$ where each P_i is an ordered tree. Because of the designation

(a) The $\mathcal{C}_3 = 5$ binary trees with 3 nodes

(b) The $\mathcal{C}_3 = 5$ ordered trees with $3 + 1 = 4$ nodes

of r as a root vertex, an ordered tree cannot be empty, unlike a binary tree.

The number of ordered trees with $n + 1$ nodes is equal to \mathcal{C}_n .

2.4 Bijections

Since Dyck Words, binary trees, and ordered trees are all Catalan objects, all three sets of objects are in bijective correspondence with each other. For convenience, we will use the \mathbf{D}_n , \mathbf{B}_n , \mathbf{E}_n , and \mathbf{T}_n to refer to the set of Dyck words of order n , the set of binary trees with n nodes, the set of extended binary trees with n internal nodes, and the set of ordered trees with $n + 2$ nodes respectively.

2.4.1 Binary Trees and Dyck Words

The bijection between extended binary trees and Dyck words is particularly elegant: For any $e \in \mathbf{E}_n$, traverse e in preorder. Record a 1 for each internal node; record a 0 for each leaf ignoring the final leaf. The resulting binary sequence is a Dyck word $D \in \mathbf{D}_n$ corresponding to the extended binary tree e . This process can be reversed to go from \mathbf{D}_n to \mathbf{E}_n .

2.4.2 Ordered Trees and Dyck Words

The bijection between ordered trees and Dyck words is particularly relevant to this paper's results, as it is central to the loopless ordered tree generation algorithm given in Chapter 3. This algorithm will use the bijection between ordered trees and Dyck words specified in Richard Stanley's *Catalan Objects* [?]. The bijection described by Stanley is as follows:¹

Given an ordered tree T with $n + 1$ nodes: Traverse T in preorder. Whenever going “down” an edge, or away from the root, record a 1. Whenever going “up” an edge, or towards the root, record a 0. The resulting binary sequence is a Dyck word D corresponding to the ordered tree T .

This process can be inverted as follows:

¹Stanley's text refers to ordered trees as *plane trees* and Dyck words as *ballot sequences*

Let T be an ordered tree with root r . Keep track of a current node c and set c equal to the root r .

- For each d_i such that $1 \leq i \leq 2n$
 - if $d_i = 1$, then add a rightmost child ch to c 's children; set $c = ch$
 - if $d_i = 0$, then set c equal to c 's parent.

In addition to the above bijection, we define the following functions relating to ordered trees, Dyck words, and the correspondence between them.

- Let $\text{OTree}(D)$ and $\text{Dyck}(T)$ be functions that convert a Dyck word to an ordered tree and an ordered tree to a Dyck word respectively via the above process.
- Let $\text{Depth}(t_i) = \text{length of path between root and } t_i$. $\text{Depth}(\text{root}) = 0$
- Let $\text{oneindex}(D, i) = \text{be the index of the } i^{\text{th}} \text{ one in } D$.

The following remarks can be derived from the bijection between ordered trees and Dyck words.

Remark 1. t_i corresponds to the i th one in D for $1 \leq i \leq n$

Proof. Recall the method of constructing an ordered tree from a Dyck word. Each one in D creates a new node; zeroes in D do not create nodes. Generating an ordered tree from a Dyck word generates the nodes of the tree in preorder. Thus, t_i corresponds to the i th one in D for $1 \leq i \leq n$. \square

Remark 2. *The difference in depths between nodes t_i and t_{i-1} is equal to one minus the number of zeroes between the $(i-1)^{st}$ and i^{th} ones in D*

Proof. This remark can be stated formally as

$$\text{Depth}(t_i) - \text{Depth}(t_{i-1}) = 1 - (\text{oneindex}(D, i) - \text{oneindex}(D, i-1) - 1) \quad (2.3)$$

Note that $(\text{oneindex}(D, i) - \text{oneindex}(D, i-1) - 1)$ is equal to the number of zeroes between the i^{th} and $(i-1)^{st}$ ones in D .

This follows naturally from the bijection between Dyck words and ordered trees. Each zero corresponds to a step up in the tree before adding the next child.

If there are zero zeroes between the i^{th} and $(i-1)^{st}$ ones in D , t_i is a child of t_{i-1} ; $\text{Depth}(t_i) = \text{Depth}(t_{i-1}) + 1$

If there is one zero between the i^{th} and $(i-1)^{st}$ ones in D , t_i is a child of t_{i-1} 's parent; $\text{Depth}(t_i) = \text{Depth}(t_{i-1}) + 1$.

Each subsequent zero between t_{i-1} and t_i decreases $\text{Depth}(t_i)$ by one. Thus, the depth of t_i is the depth of t_{i-1} plus 1 minus the number of zeroes between t_{i-1} and t_i . \square

Remark 3. *A preorder listing of $\text{Depth}(t_i)$ for each $t_i \in T$ can be used to construct a Dyck word.*

Proof. Let $T = t_0, t_1, \dots, t_n$ be a preorder traversal of T . Note that t_0 is the root of T

Construct D as follows:

- Let $D = \epsilon$
- For each t_i , $1 \leq i \leq n$
 - Append a 1 to D
 - Append $1 - \text{Depth}(t_i) + \text{Depth}(t_{i-1})$ zeroes to D .
- Append $\text{Depth}(t_n)$ zeroes to D .

\square

2.5 Cool Lex Order on Dyck Paths and Binary Trees

TODO: probably move this to a different chapter, also fix notation to be consistent.

Ruskey and Williams found the following successor rule for enumerating binary Dyck words, dubbed “CoolCat” due to its use of a cool-lex order to generate (cat)alan objects [?]: We will use \mathbf{D}_n to denote binary Dyck words with n ones and n zeroes. Note that the length of any string in \mathbf{D}_n is thus $2n$.

Let $D \in \mathbf{D}_n$

Let the i th prefix shift of D , denoted by $\text{preshift}(D, i)$, be a function that rotates the second through i th symbols of D one to the right circularly. More formally,

$$\text{preshift}(d, i) = d_1, d_i, d_2, \dots, d_{i-1}, d_{i+1}, d_{i+2}, \dots, d_{2n}$$

Let k be the index of the 1 in the leftmost 01 substring in D if it exists. Note that if D has no 01 substring, then $D = 1^n 0^n$. The successor rule for D is as follows:

$$\overrightarrow{\text{coolCat}}(D) = \begin{cases} \text{preshift}(D, 2n) & \text{if } D \text{ has no 01 substring} & (2.4a) \\ \text{preshift}(D, k+1) & \text{if } \text{preshift}(D, k+1) \in \mathbf{D}_n & (2.4b) \\ \text{preshift}(D, k) & \text{otherwise} & (2.4c) \end{cases}$$

Ruskey and Williams’s algorithm can also enumerate a broader set of strings: The algorithm enumerates any set $\mathbf{D}_{s,t}$ where any $D \in \mathbf{D}_{s,t}$ has s zeroes and t ones and satisfies the constraint that each prefix of D has as many ones as zeroes. This is slightly broader than the language of Dyck words,

as it does not have the requirement that a string have an equal number of ones and zeroes. We will focus on \mathbf{D}_n languages due to their correspondence with Dyck words and therefore other Catalan objects.

Evaluating whether $\text{preshift}(D, k+1) \in \mathbf{D}_n$ can be determined by looking D_{k+1} and the sum of the first k symbols of D :

Let $D' = \text{preshift}(D, k+1)$

Note that we know $D \in \mathbf{D}_n$.

Since preshift only rotates symbols, D' will automatically satisfy the requirement that strings in \mathbf{D}_n must have an equal number of zeroes and ones since D satisfied that requirement. Thus, $D' \in \mathbf{D}_n$ will be determined by whether or not all prefixes of D' have at least as many ones as zeroes.

If D_{k+1} is a 1, then for all i , the i^{th} prefix of D' will have at least as many ones as the i^{th} prefix of D . Thus, D' must be $\in \mathbf{D}_n$, as rotating a 1 to earlier in the string will never invalidate the requirement that every prefix of the string has at least as many ones as zeroes.

Note that the k^{th} prefix of D must be of the form $1^a 0^b$, as otherwise there would be an earlier 01 prefix. Furthermore, $a \geq b$ as otherwise the b^{th} prefix of D would have more zeroes than ones and D would not be a valid Dyck word.

If D_{k+1} is a 0, then $D' \notin \mathbf{D}_n$ if and only if rotating a 0 to index 2 creates a prefix of D with more zeroes than ones. This will only happen if the $(k-1)^{\text{th}}$ prefix of D is exactly $1^{\frac{k-1}{2}} 0^{\frac{k-1}{2}}$.

Therefore, $\text{preshift}(D, k+1) \in \mathbf{D}_n \iff D_{k+1} = 1$ or D starts with more than $\lfloor \frac{k-1}{2} \rfloor$ ones

$$\overrightarrow{\text{coolCat}}(D) = \begin{cases} \text{preshift}(D, 2n) & \text{if } D \text{ has no 01 substring} & (2.5a) \\ \text{preshift}(D, k+1) & D_{k+1} = 1 \text{ or } D \text{ starts with more than } \lfloor \frac{k-1}{2} \rfloor \text{ ones} & (2.5b) \\ \text{preshift}(D, k) & \text{otherwise} & (2.5c) \end{cases}$$

Since k is the index of the first 01 substring in D , $\sum_{i=1}^k S_i$ is actually just the number of consecutive ones to start D , which simplifies the evaluation of this conditional even further.

Ruskey and Williams provided a loopless pseudocode implementation of CoolCat that utilized this fact to enumerate any $\mathbf{D}_{s,t}$ using at most 2 conditionals per successor [?].

Due to its simplicity and efficiency, Don Knuth included the cool-lex algorithm for Dyck words in his 4th volume of *The Art of Computer Programming* and also provided an implementation of it for his theoretical MMIX processor architecture [?].

Chapter 3

Loopless Ordered Tree Generation

This chapter presents the first loopless algorithm for generating all ordered trees with n nodes.

Ruskey and Williams previously gave a cool-lex algorithm for looplessly generating all Dyck words of a given length via prefix shifts [?]. In the same paper, Ruskey and Williams also gave a loopless algorithm for generating all binary trees with a fixed number in the same order.

This thesis provides a new algorithm that generates ordered trees with a fixed number of nodes in a cool-lex order. The algorithm generates a minimal change ordering of ordered trees in the same order as their corresponding Dyck words in Ruskey and Williams’s paper. Like the cool-lex algorithms for Dyck words and binary trees, this algorithm can be implemented looplessly: each ordered tree takes worst-case constant time to generate. This is faster than other algorithms for generating ordered trees which take constant amortized time [?] [?] [?] [?]. Moreover, taken in conjunction with Ruskey and Williams’s algorithms for Dyck words and binary trees, this algorithm completes a trio of loopless cool-lex algorithms for enumerating the three foremost Catalan structures.

Parque and Miyashita present a constant amortized time algorithm for generating ordered trees, claiming that it operates “with utmost efficiency” [?]. Our algorithm operates in worst-case constant time per tree, which is faster. To borrow Parque and Miyashita’s terminology, perhaps we should say that our algorithm operates with *utmost* efficiency

Like the cool-lex algorithm for binary trees, this algorithm generates ordered trees stored as pointer structures. This contrasts from other efficient gray codes for enumerating ordered trees, which use either bit-strings or integer sequences to represent ordered trees [?] [?] [?] as representations of ordered trees. Skarbek’s 1988 paper *Generating Ordered Trees* gives a constant amortized time algorithm for generating ordered trees stored as pointer structures and is therefore a notable exception to this [?]. Generating ordered trees via a pointer structure facilitates the practical use of the trees generated by this algorithm, as a translation step between an alternative representation and a tree structure to traverse the tree is not necessary.

3.1 Successor Rule

Let F be the leftmost leaf of T , or equivalently the leftmost descendant of the root. Consider the unique path between the root of T and F , denoted $\text{path}(T, \text{root}, F)$. We will refer to this path as the left-down path of T , or $\text{leftpath}(T)$

Given an ordered tree T , let O be the first node in a preorder traversal of T that is not in the $\text{path}(T, \text{root}, F)$. If $\text{path}(T, \text{root}, F) = T$, i.e. the entire tree is a single path, let O be the leaf of the tree. Let P be O ’s parent. Let G be P ’s parent, and let L be P ’s leftmost child (or, equivalently, O ’s left sibling). The labels P , G , and L are mnemonics for O ’s (p)arent, (g)randparent, and (l)eft sibling. Fig. 3.3 gives an example illustrating O, P, G, L, F , and the left-down path in an tree.

Given an ordered tree T and an ordered tree node A in T , let $\text{popchild}(A)$ be a function that removes and returns A ’s first child. In other words, it pops A ’s first child.

Additionally, let $\text{pushchild}(A, B)$ be a function that makes B A ’s first child. In other words, it pushes B onto A ’s list of children.

For convenience, we will also define $\text{poppush}(A, B) = \text{pushchild}(B, \text{popchild}(A))$, which removes the first child of A and makes it the new first child of B .

Figure 3.1: An ordered tree with 12 nodes corresponding to the Dyck word 1111110000110010011000. The left down path of T is highlighted in purple.

The successor rule for enumerating ordered trees with n nodes can be stated as follows:

$$\text{nexttree}(T) = \begin{cases} \text{poppush}(P, G); \text{poppush}(P, \text{root}) & P \neq \text{root} \text{ and } O \text{ has no children} \\ \text{poppush}(P, O) & \text{otherwise} \end{cases} \quad (3.1a)$$

$$(3.1b)$$

Figure 3.2 gives a demonstration of the shifts in cases 3.1a and 3.1b

To make the order cyclic, an additional rule can be added, modifying the successor rule to be:

$$\text{nexttree}(T) = \begin{cases} \text{poppush}(P, \text{root}) & \text{leftpath}(T) = T \\ \text{poppush}(P, G); \text{poppush}(P, \text{root}) & P \neq \text{root} \text{ and } O \text{ has no children} \\ \text{poppush}(P, O) & \text{otherwise} \end{cases} \quad (3.2a)$$

$$(3.2b)$$

$$(3.2c)$$

TODO: general illustration

The following remarks can be derived from the definition of the successor rule and the nodes O, G, L , and T .

Let $D = \text{Dyck}(T)$; s be the number of consecutive ones to start D , and z be the number of consecutive zeroes starting at d_{s+1} . Note that $z = (k - s - 1)$; $d_k = 1$

Remark 4. $\text{Depth}(O) = s - z + 1$

Proof. t_s is the last node in the $\text{leftpath}(T)$, as the left-down path has $s + 1$ nodes starting at t_0 . t_s has depth s , as it is exactly s steps from the root. Note that $O = t_{s+1}$. The number of zeroes between t_s and t_{s+1} is the number of zeroes between the s^{th} and $(s + 1)^{\text{st}}$ ones in D_i . □

Remark 5. O corresponds to D_k , i.e. $\text{oneindex}(D, s + 1) = k$

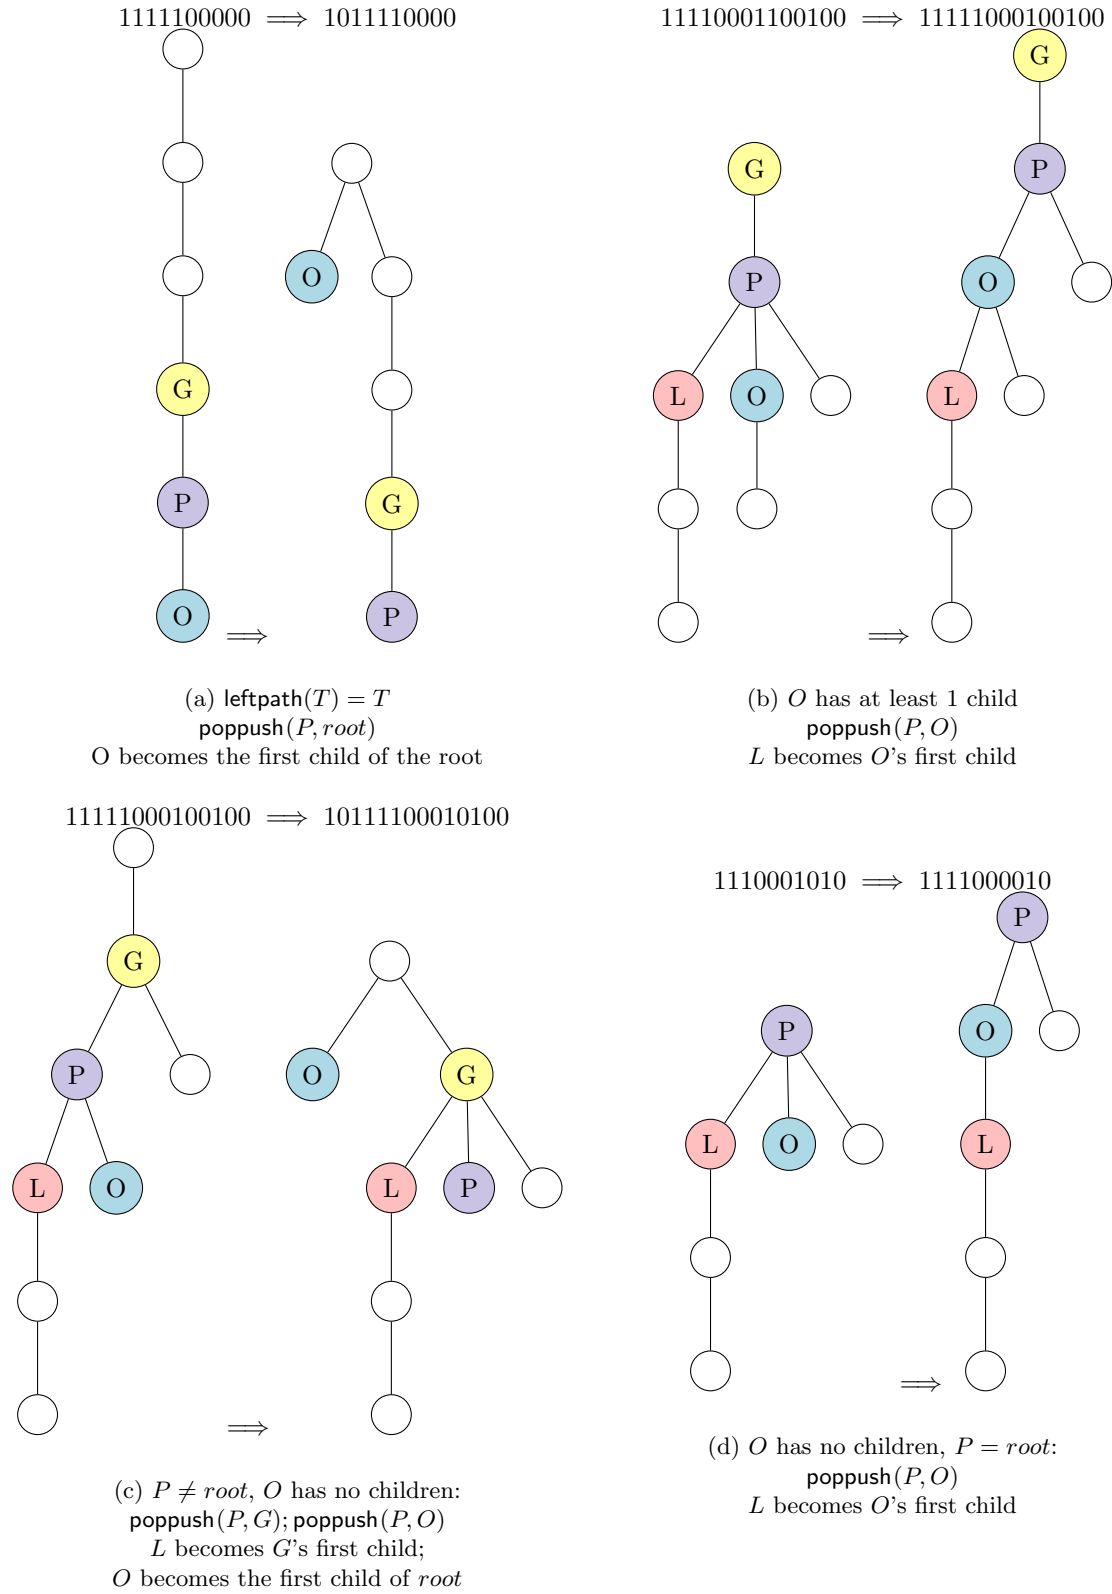

Figure 3.2: Illustrations of the 4 cases of the expanded definition of $\text{nexttree}(T)$ in 3.3

Proof. Let $D = \text{Dyck}(T)$ and let k be the index of the 1 in the leftmost 01 substring of D . Let $t_0 \dots t_s = \text{leftpath}(T)$; $O = t_{s+1}$.

Note that each 1 in D corresponds to a step down; each 0 to a step up. Consequently, $\text{leftpath}(T)$ corresponds to the “all-one” prefix of D . In other words, $\text{leftpath}(T) = t_0, t_1, \dots, t_s$ such that $i = 0$ or $D_i = 1$. Note that t_{s+1} is therefore the first node in a preorder traversal of T such that $D_{\text{oneindex}(D, s+1)} = 1$ and $D_{\text{oneindex}(D, s+1)-1} = 0$. O is therefore also the first node in a preorder traversal of T such that $t_{s+1} \notin \text{leftpath}(T)$. Therefore, $\text{oneindex}(D, s+1) = k$, i.e., $t_{s+1} = O$ corresponds to the 1 in the leftmost 01 substring of D . \square

Remark 6. Every non-leaf node below P in $\text{leftpath}(T)$ has exactly 1 child.

Proof. Suppose by way of contradiction that a node below P in $\text{leftpath}(T)$ had a second child. That child would not be in $\text{leftpath}(T)$ and would be traversed before O in preorder. O was specified to be the first node in a preorder traversal of T that is not in $\text{leftpath}(T)$, which generates a contradiction. \square

Remark 7. L corresponds to D_{s-z+1} , i.e. $\text{oneindex}(D, s-z+1) = s-z+1$

Proof. $\text{Depth}(L) = \text{Depth}(O) = s-z-1$ since L and O are siblings. Therefore, L must be $s-z-1$ steps down from the root $\implies L$ is the $s-j-1$ th node in a preorder traversal of $T \implies T$ corresponds to D_{s-z-1} . \square

3.2 Proof of Correctness

Ruskey and Williams proved that, given a Dyck word of order n , 2.5 iteratively generates all Dyck words of order n . This proof will use the bijection between Dyck words of order n and ordered trees with $n+1$ nodes to show that that 3.1 generates all ordered trees with a given number of nodes.

Recall that the successor rule $\text{coolCat}(D)$ generates all Dyck words. Therefore, To prove that $\text{nexttree}(T)$ generates all ordered trees with $|T|$ nodes, it is sufficient to show that, given an arbitrary ordered tree T ,

Theorem 3.2.1. Given an ordered tree T , $\text{nexttree}(T) = \text{OTree}(\overrightarrow{\text{coolCat}}(\text{Dyck}(T)))$

Proof. $\overrightarrow{\text{coolCat}}(D)$ and $\text{nexttree}(T)$ are each broken down into 3 cases in equations 2.5 and 3.1 respectively.

For convenience, equations 3.3 and 3.4 give the expanded restatements of the successor rules for $\text{nexttree}(T)$ and $\overrightarrow{\text{coolCat}}(D)$ to facilitate comparisons between the two.

$$\text{nexttree}(T) = \begin{cases} \text{poppush}(P, \text{root}) & \text{leftpath}(T) = T & (3.3a) \\ \text{poppush}(P, O) & \text{if } O \text{ has at least 1 child} & (3.3b) \\ \text{poppush}(P, G); \text{poppush}(P, \text{root}) & \text{if } P \neq \text{root} \text{ and } O \text{ has no children} & (3.3c) \\ \text{poppush}(P, O) & \text{if } O \text{ has no children and } P = \text{root} & (3.3d) \end{cases}$$

$$\overrightarrow{\text{coolCat}}(D) = \begin{cases} \text{preshift}(D, 2n) & \text{if } D \text{ has no 01 substring} & (3.4a) \\ \text{preshift}(D, k+1) & D_{k+1} = 1 & (3.4b) \\ \text{preshift}(D, k+1) & D_{k+1} = 0 \text{ and } s > \frac{k-1}{2} & (3.4c) \\ \text{preshift}(D, k) & D_{k+1} = 0 \text{ and } s = \frac{k-1}{2} & (3.4d) \end{cases}$$

We will show the following equivalences:

- 3.3a corresponds to 3.4a
- 3.3b corresponds to 3.4b

- 3.3c corresponds to 3.4c
- 3.3d corresponds to 3.4d

To accomplish this, we will first prove a few auxillary lemmas to be used to show equivalency between cases.

Let $D = \text{Dyck}(T)$, s be the number of consecutive ones to start D , and z be the number of consecutive zeroes starting at d_{s+1} . Note that $z = (k - s - 1)$; $d_k = 1$

Lemma 3.2.2. D has no 01 substring $\iff \text{leftpath}(T) = T$

Proof. If D has no 01 substring, $D = 1^n 0^n$, and T is $n + 1$ nodes where t_0 is the root and each t_i for $1 \leq i \leq n$ is a child of t_{i-1} . In this case, T is a single path of $n + 1$ nodes, and the left-down path of T is the entire tree. \square

Lemma 3.2.3. $D_{k+1} = 0 \iff O$ has no children

Proof. This follows logically from the bijection between Dyck words and ordered trees. D_k corresponds to O . If $D_{k+1} = 0$, an “upward” step is taken after O and consequently the next node after O cannot be a child of O . Since the ones in D give the nodes of T in preorder, O must have no children.

Informally, once you go “up” from O , the bijection between Dyck words and ordered trees gives no way to go “back down” to give O an additional child. \square

Lemma 3.2.4. $P = \text{root} \iff s = z = \frac{k-1}{2}$.

Proof. First, note that $P = \text{root}$ simply means that O is a child of the root. O is a child of the root $\iff \text{Depth}(O) = 1$. Additionally, note that $s + z = k - 1$

As shown in remark 4, $\text{Depth}(O) = s - z + 1$. Therefore, $P = \text{root} \iff s = z = \frac{k-1}{2}$ i.e. the first $k - 1$ symbols of D are $\frac{k-1}{2}$ ones followed by $\frac{k-1}{2}$ zeroes. \square

Lemma 3.2.5. 3.3a corresponds to 3.4a

Proof. Let $D = \text{Dyck}(T)$

Per lemma 3.2.2 D has no 01 substring $\iff \text{leftpath}(T) = T$.

Thus, $\text{nextree}(T)$ executes case 3.3a if and only if $\text{coolCat}(D)$ executes case 3.4a

Note that since D has no 01 substring, $D = 1^n 0^n$.

Additionally, since $\text{leftpath}(T) = T$, T can be specified as follows.

$T =$

node	t_0	t_1	t_2	\dots	t_{n-1}	$F = t_s = t_n$
depth	0	1	2	\dots	$n - 1$	n
Dyck		$1^n 0^n$				

The third row of this table illustrates the construction of $\text{Dyck}(T)$ via the process specified in remark 3.

Shifting F to be the first child of the root changes $\text{Depth}(F)$ to 1 and does not affect the depth of any other nodes. Thus, if $T' = \text{nextree}(T)$,

$T =$

node	t_0	$F = t_s = t_n$	t_1	t_2	\dots	t_{n-1}
depth	0	1	1	2	\dots	$n - 1$
Dyck		1	$01^{n-1} 0^{n-1}$			

Recall that $\text{coolCat}(D) = \text{preshift}(D, 2n)$ if D has no 01 substring. $D_{2n} = 0$, and therefore $\text{coolCat}(D) = 101^{n-1} 0^{n-1}$

Note that this is exactly the Dyck word constructed from T' . Therefore, if D has no 01 substring or $\text{leftpath}(T) = T$,

$\text{OTree}(\text{coolCat}(D)) = \text{nextree}(T)$

\square

Lemma 3.2.6. 3.3c corresponds to 3.4c

Proof. Let $D = \text{Dyck}(T)$

Per lemma 3.2.4 $P = \text{root} \iff D$ starts with exactly $\frac{k-1}{2}$ ones.

It was also previously shown that $D_{k+1} = 0 \iff O$ has no children. Thus, $\text{nexttree}(T)$ executes case 3.1a if and only if $\text{coolCat}(D)$ executes case 3.4c

We now show that the execution of 3.1a is equivalent to the execution of 3.4c given case a. Given $\text{Dyck}(T) = D = 1^s 0^z 10 \overrightarrow{d_{k+2} d_{k+3} \dots d_{2n}}$, we aim to show that

$$\text{Dyck}(\text{nexttree}(T)) = \text{coolCat}(\text{Dyck}(T))$$

Note that in this case $\text{nexttree}(T)$ can be obtained by performing $\text{poppush}(P, G); \text{poppush}(P, \text{root})$.

Let $T' = \text{poppush}_T(P, G); T'' = \text{poppush}_{T'}(P, \text{root})$

Note that $\text{nexttree}(T) = T''$

Since $P \neq \text{root}$, we know that G , the parent of P , exists. Thus, we can assume that $G, P, L \in \text{leftpath}(T)$. T can therefore be specified as follows:

$$T =$$

<i>node</i>	t_0	t_1	\dots	$G = t_{s-z-1}$	$P = t_{s-z}$	$L = t_{s-z+1}$	\dots	$F = t_s$	$O = t_{s+1}$	\dots
<i>depth</i>	0	1	\dots	$(s-z-1)$	$(s-z)$	$(s-z+1)$	\dots	s	$(s-z+1)$	\dots
<i>Dyck</i>				1^s					$0^z 1$	$0 \dots$

Furthermore, recall that L (and all other non-leaf nodes $\in \text{leftpath}(T)$) must have exactly one child. Therefore, every node below L in $\text{leftpath}(T)$ has its depth reduced by one; no other nodes have their depth affected by this shift. Therefore, T' can be written as follows:

$$T' =$$

<i>node</i>	t_0	t_1	\dots	$G = t_{s-z-1}$	$L = t_{s-z+1}$	\dots	$F = t_s$	$P = t_{s-z}$	$O = t_{s+1}$	\dots
<i>depth</i>	0	1	\dots	$(s-z-1)$	$(s-z)$	\dots	$s-1$	$(s-z)$	$(s-z+1)$	\dots
<i>Dyck</i>				1^{s-1}				$0^z 1$	1	$0 \dots$

Since L is now G 's first child, P changes from being G 's first child to G 's second child. P is therefore removed from the left-down path of T' , thereby making P the first node in a preorder traversal of T' that is not in the left-down path of T' . Therefore, $|\text{leftpath}(T')| = s; O' = P$.

Recovering a Dyck word from T' , we obtain

$$D' = 1^{s-1} 0^z 110 \overrightarrow{d_{k+2} d_{k+3} \dots d_{2n}}$$

Next, we use $\text{poppush}_{T'}(P, \text{root})$ to obtain $T'' = \text{nexttree}(T)$

$\text{poppush}_{T'}(P, \text{root})$ shifts O to become the first child of the root. Note that we know that O has no children. Consequently, no nodes other than O have their depth affected by this shift. Thus,

$$T'' =$$

<i>node</i>	t_0	$O = t_{s+1}$	t_1	t_2	\dots	$G = t_{s-z-1}$	$L = t_{s-z+1}$	\dots	$F = t_s$	$P = t_{s-z}$	\dots
<i>depth</i>	0	1	1	2	\dots	$(s-z-1)$	$(s-z)$	\dots	$s-1$	$(s-z)$	\dots
<i>Dyck</i>		1				01^{s-1}				$0^z 1$	\dots

Therefore, since $T'' = \text{nexttree}(T)$, $\text{Dyck}(\text{nexttree}(T)) = 101^{s-1} 0^z 1 \dots$

Since $\text{Dyck}(T) = D = 1^s 0^z 10 \dots$ 3.4b gives that

$$\text{coolCat}(\text{Dyck}(T)) = 101^{s-1} 0^z 1 \dots$$

Therefore, we have shown that $\text{Dyck}(\text{nexttree}(T)) = \text{coolCat}(\text{Dyck}(T)) = 101^{s-1} 0^z 1 \dots$

□

Lemma 3.2.7. 3.3b corresponds to 3.4b

Proof. Per 3.2.3, as O has at least 1 child $\iff D_{k+1} = 1$.

Thus, $\text{nextree}(T)$ will execute case 3.3b if and only if $\overrightarrow{\text{coolCat}}(D)$ executes case 3.4b

Therefore, we aim to show that, given O has at least one child and $D_{k+1} = 1$,

$\text{preshift}(\text{Dyck}(T), k+1) = \text{Dyck}(\text{poppush}_T(P, O))$

Since $D_{k+1} = 1$, we can rewrite D as. $D = 1^s 0^z 11$

$T =$

<i>node</i>	t_0	t_1	\dots	$G = t_{s-z-1}$	$P = t_{s-z}$	$L = t_{s-z+1}$	\dots	$F = t_s$	$O = t_{s+1}$	$t_{s+2} \dots$
<i>depth</i>	0	1	\dots	$(s-z-1)$	$(s-z)$	$(s-z+1)$	\dots	s	$(s-z+1)$	$s-z+2 \dots$
<i>Dyck</i>				1^s					$0^z 1$	$1 \dots$

$\text{poppush}_T(P, O)$ shifts L to be O 's first child:

Nodes $L = t_{s-z+1}$ through $F = t_s$ will now come after O in preorder traversal. Additionally, $\text{leftpath}(T)$ will now go through O ; every node in $\text{path}(T, L, F)$ will have its depth increased by one.

Therefore, $T' = \text{nextree}(T)$ can be specified as follows:

$T' =$

<i>node</i>	t_0	t_1	\dots	$G = t_{s-z-1}$	$P = t_{s-z}$	$O = t_{s+1}$	$L = t_{s-z+1}$	\dots	$F = t_s$	$t_{s+2} \dots$
<i>depth</i>	0	1	\dots	$(s-z-1)$	$(s-z)$	$(s-z+1)$	$(s-z+2)$	\dots	$s+1$	$s-z+2 \dots$
<i>Dyck</i>				1^{s+1}					$0^z 1 \dots$	

Note that $z \geq 1$, so z zeroes occur between the one corresponding to t_s and the one corresponding to t_{s+2} .

Next, recall that $D = \text{Dyck}(T) = D = 1^s 0^z 11 \dots$ and that $k = s + z + 1$

Therefore, $\overrightarrow{\text{coolCat}}(D) = \text{preshift}(D, k+1) = 1^{s+1} 0^z 1 \dots$, which is the same as the Dyck word resulting from translating $T' = \text{nextree}(T)$ to the Dyck word $1^{s+1} 0^z 1 \dots$

□

Lemma 3.2.8. 3.3d corresponds to 3.4d

Proof. $T \neq \text{leftpath}(T) \iff D$ has a 01 substring.

$D_{k+1} = 1 \iff O$ has at least one child.

$D_{k+1} = 0$ and $s = \frac{k-1}{2} \iff O$ has no children and O is a child of the root.

O has no children and $P = \text{root}$. Therefore $s = z$, $k = 2s + 1$

We can thus rewrite $D = \text{Dyck}(T) = 1^s 0^s 101 \dots$

Furthermore, since $s = z$, O has depth 1.

Therefore, we can write T as $T =$

<i>node</i>	$P = t_0$	$L = t_1$	\dots	$F = t_s$	$O = t_{s+1}$	$t_{s+2} \dots$
<i>depth</i>	0	1	\dots	s	1	1
<i>Dyck</i>			1^s		$0^s 1$	$01 \dots$

$\text{poppush}_T(P, O)$ shifts L to be O 's first child:

Therefore, nodes $L = t_1$ through $F = t_s$ will now come after O in preorder traversal. Additionally, $\text{leftpath}(T)$ will now go through O ; every node in $\text{path}(T, L, F)$ will have its depth increased by one.

Therefore, $T' = \text{nextree}(T)$ can be specified as follows:

$T' =$

<i>node</i>	$P = t_0$	$O = t_{s+1}$	$L = t_1$	\dots	$F = t_s$	$t_{s+2} \dots$
<i>depth</i>	0	1	2	\dots	$s+1$	1
<i>Dyck</i>			1^{s+1}			$0^{s+1} 1 \dots$

Since $D = \text{Dyck}(T) = 1^s 0^s 101 \dots$, $\overrightarrow{\text{coolCat}}(D) = 1^{s+1} 0^{s+1} 1 \dots$ as per case 3.3d. This is identical to the Dyck word constructed from $T' = \text{nextree}(T)$. Therefore, cases 3.3d and 3.4d are equivalent.

□

Since these 4 cases cover all cases for the two successor rules, we have shown that $\text{nextree}(T) = \text{OTree}(\overrightarrow{\text{coolCat}}(\text{Dyck}(T)))$ in all cases.

□

Figure 3.3: The initial trees returned by `get_initial_tree` in `cool0tree` with $t = 1, 2, 3$, and 4. Note the convenient feature that for each tree, `O` is equal to `root->left_child->right_sibling`.

3.3 Loopless Implementation

The algorithm described in this section has been implemented in C using a tree node struct that contains fields for each node's parent, leftmost child (firstborn), and right sibling.

The functions `shift_tree_a` and `shift_tree_b` perform the shifts outlined in cases 3.1a and 3.1b respectively; the function `get_initial_tree` generates the first tree in the ordering.

`t` is a parameter equal to the number of non-root nodes in the tree; `visit` is a user-supplied function for visiting a tree.

<p>Generate all ordered trees with $t + 1$ nodes</p> <pre> function COOL-ORDERED-TREES(t) ▷ Generate initial tree $O \leftarrow \text{root.lchild}$ visit(root) while $O \neq \text{NULL}$ do $P \leftarrow O.\text{parent}$ if $O.\text{lchild} \neq \text{NULL}$ then pushchild(O, popchild(P)) $O \leftarrow O.\text{lchild}.\text{rsibling}$ else if $O.\text{parent} == \text{root}$ then pushchild(O, popchild(P)) else pushchild(O, popchild(P)) pushchild(root, popchild(P)) $O \leftarrow O.\text{rsibling}$ visit(root) </pre>	<pre> void cool0tree(int t, void (*visit)(node*)) { node* root = get_initial_tree(t); node* o = root->left_child->right_sibling; visit(root); while(o) { node* p = o->parent; if(o->left_child) { pushchild(o, popchild(p)); o = o->left_child->right_sibling; } else { if(o->parent == root) { pushchild(o, popchild(p)); } else { pushchild(p->parent, popchild(p)); pushchild(root, popchild(p)); } o = o->right_sibling; } visit(root); } } </pre>

Loopless (?) Lukasiewicz Word Generation

4.0.1 Lukasiewicz Path Successor Rule

The successor rule for Lukasiewicz paths is as follows:

Let S be a multiset whose sum is equal to its length. Let $\mathcal{L}(S)$ denote the set of valid Lukasiewicz words with content equal to S . Let $\alpha \in \mathcal{L}(S)$.

Let m be the maximum value such that $\alpha_{i-1} \geq \alpha_i$ for all $2 \leq i \leq m$. In other words, let m be the length of the non-increasing prefix of α .

$$\overleftarrow{\text{luka}}(\alpha) = \begin{cases} \text{left}(n, 2) & \text{if } m = n \\ \text{left}(m+1, 1) & \text{if } m = n-1 \text{ or } \alpha_m < \alpha_{m+2} \text{ or} \\ & (\alpha_{m+2} = 0 \text{ and } \sum \rho = m) \\ \text{left}(m+2, 1) & \text{if } \alpha_{m+2} \neq 0 \\ \text{left}(m+2, 2) & \text{otherwise} \end{cases}$$

In addition to generating Lukasiewicz words, this successor rule also

Chapter 5

Loopless Motzkin Word Generation

5.0.1 Loopless Motzkin Generation

Since Lukasiewicz words are a generalization of Motzkin words, the same algorithm can be used to generate Motzkin words by restricting the content set S to be strictly zeroes, ones, and twos. However, the additional restrictions on Motzkin words allow for a simpler implementation of the rule. Pseudocode for loopless generation of Motzkin words is given below in Fig. 5.1.

Let m be the length of the longest non-increasing prefix of α .

$$\overleftarrow{\text{motzkin}}(\alpha) = \begin{cases} \text{left}(n, 2) & \text{if } m = n \\ \text{left}(m + 1, 1) & \text{if } m = n - 1 \text{ or } \alpha_m < \alpha_{m+2} \text{ or} \\ & (\alpha_{m+2} = 0 \text{ and } \sum \rho = m) \\ \text{left}(m + 2, 1) & \text{if } \alpha_{m+2} \neq 0 \\ \text{left}(m + 2, 2) & \text{otherwise} \end{cases}$$

Algorithm 1 Motzkin

```
function COOLMOTZKIN( $s, t$ )  
   $n \leftarrow 2 * s + t$   
   $b \leftarrow 2^1 0^1 2^{s-1} 1^t 0^{s-1}$   
   $x \leftarrow 3$   
   $y \leftarrow 2$   
   $z \leftarrow 2$   
  visit( $b$ )  
  while  $x \leq n$  do  
     $q \leftarrow b_{x-1}$   
     $r \leftarrow b_x$   
  
     $b_x \leftarrow b_{x-1}$   
     $b_y \leftarrow b_{y-1}$   
     $b_z \leftarrow b_{z-1}$   
     $b_1 \leftarrow r$   
  
     $x \leftarrow x + 1$   
     $y \leftarrow y + 1$   
     $z \leftarrow y + 1$
